Q6. Which of the following technologies are required for a company to digitally transform industrial operations? Select all that apply. (Total n=250; Manufacturing n=50; Aviation/Aerospace n=50; Transportation n=50; Utilities n=50; Power/Energy n=50)

*Top 3 listed unless there is a tie

Size and market impact of IIoT

IIoT market by 2021

\$123bn

IndustryARC ((2016):
\$123.89 Billion by 2021

CAGR until 2020

7.3%

Global IIOT Market report:
Global IIoT market to grow at
a CAGR of 7.3% until 2020.

The Internet of Things - Botnets

- But many IoT devices often remain unprotected and targets of botnets

The screenshot shows a news article layout. At the top left is the 'Krebs on Security' logo with the tagline 'In-depth security news and in'. To its right is the 'WIRED' logo. Further right is a headline: 'The Reaper IoT Botnet Has Already Infected a Million Networks'. Below this is a byline: 'ANDY GREENBERG SECURITY 10.20.17 05:45 PM'. The main content area features the 'ars TECHNICA' logo on the left and a navigation bar with links: 'BIZ & IT', 'TECH', 'SCIENCE', 'POLICY', 'CARS', and 'GAMING & CULTURE'. The article title is 'INTERNET OF BROKEN THINGS — A potent botnet is exploiting a critical router bug that may never be fixed'. Below the title is a sub-headline: 'With Internet stability hanging in the balance, router maker maintains radio silence.' At the bottom left of the article is the author and date: 'DAN GOODIN - 2/14/2018, 2:10 PM'.

Satori Botnet Is Now Attacking Ethereum Mining Rigs

By [Catalin Cimpanu](#) January 17, 2018 05:05 AM 0

The Internet of Things (cont.)

- DDoS attacks increased 91% in 2017 thanks to IoT
 - Criminals can now attack and take down a company for less than \$100

Source-end DDoS Defense

- Detects and thwarts attack traffic before the traffic leaves its original network
 - Easier to properly handle DDoS attacks near the attack sources
 - Can play a pivotal role in collaborative DDoS defenses
 - Guarantees impunity when a collaborator is under attack
- Source-end DDoS defenses operate in three main phases:
 1. Attack Detection
 - (eg) receive an attack notification from a collaborator
 2. Traffic Classification
 - (eg) label current connections as good or bad
 3. Attack Response
 - (eg) filter the bad connections and allow safe passage for the good

Source-end DDoS Defense in IoT Networks

- False positives are significantly detrimental in IoT environments
 - False positive = misidentifying a benign connection as malicious
 - Filtering a benign connection results in:
 - Unnecessary retransmission
 - Reduced goodput
 - Excessive energy consumption (loss of precious battery life)
- Must still maintain close to zero false negatives
 - False negative = misidentifying a malicious connection as benign
 - Allowing safe passage of malicious connections fails to mitigate an attack
- Categorically labeling traffic as good or bad becomes extremely difficult

Crux of the Problem

- A source-end DDoS defense will unavoidably encounter traffic it must label with low confidence
 - We call this traffic **suspicious**
- If the defense filters the suspicious traffic:
 - It inevitably filters some good traffic
 - Leads to unwanted negative effects on benign traffic in IoT networks
- If the defense allows safe passage for the suspicious traffic:
 - It inevitably allows safe passage for some bad traffic
 - Fails to comprehensively mitigate an attack
- We need an efficient—but effective—**response** to suspicious traffic

Table of Contents

1. Introduction

- The Internet of Things
- Source-end Distributed Denial-of-Service Defense
- Difficulties of Source-end Defense for the Internet of Things

2. FR-WARD

- Threat Model & Assumptions
- Basic Design
- Labeling Procedure
- Signaling Mechanism
- Defending Against Smart Attackers
- Extending the Signaling Mechanism

3. Evaluation

- Effects on Benign Traffic
- Effects on Malicious Traffic

Threat Model & Assumptions

- FR-WARD is placed at the gateway of a generic IoT environment
 - The IoT network maintains wireless connectivity between low power, energy constrained devices
 - The IoT network could be:
 - a smart home
 - a Wireless Sensor Network (WSN)
 - a smart city, etc

Threat Model & Assumptions (cont.)

- FR-WARD has two main goals:
 1. Throttle **all** malicious DDoS traffic that attempts to leave the policed network to harmless sending rates
 2. Throttle **no** benign traffic that attempts to leave the policed network during this process

Basic Design

- The design of FR-WARD is driven by the fundamental characteristics of an IoT environment
- It follows two principles:
 1. It adopts a conservative approach to avoid dropping benign traffic
 - FR-WARD will **not** drop **any** traffic it cannot definitively discern as malevolent
 - Instead devises a signaling mechanism to handle suspicious connections
 2. The defense cannot rely on installation of new hardware or software on IoT devices
 - Instead relies only on protocols and functions that the IoT devices already support

Basic Design (cont.)

FR-WARD's flexible architecture

Labeling Procedure

- It is not the main focus of FR-WARD to improve detection or classification of an attack
 - Connection labels act as an input to the FR-WARD system
- FR-WARD uses the observation component of the previous source-end DDoS defense solution D-WARD
 - Can instead rely on any connection labeling procedure that categorizes traffic into good, suspicious, or bad
 - (e.g.) Victim-end collaboration, machine learning, etc

Labeling Procedure (cont.)

- D-WARD monitors traffic at two levels of granularity:
 1. Classifies the aggregate traffic from the *entire* source network to a particular host as an **agflow**
 - Labels deviations from a predefined normal model as *attack agflows*
 2. Further classifies the aggregate traffic from *one node* in the source network to a particular host as an **connection**
 - Labels deviations from a predefined normal model as *bad connections*

Signaling Mechanism

- Good and bad connections are easy to respond to:
 - Throttle bad connections and allow safe passage of good connections
- FR-WARD must also respond to suspicious connections
 - Employs the fast retransmit mechanism from TCP congestion control to reduce their sending rate
- FR-WARD sends three duplicate acknowledgements of an “in-flight” segment to the suspicious connection
 - The sender cuts its window size in half and immediately retransmits the “in-flight” segment
 - In accordance to multiplicative decrease and fast retransmit
- We call this set of duplicate acknowledgements a **signal**

Signaling Mechanism: TCP Reno

Signaling Mechanism: TCP Reno

Signaling Mechanism: TCP Reno

Signaling Mechanism: TCP Reno

Signaling Mechanism: Benefits

1. Identifies compliance with congestion control

- FR-WARD can relabel non-compliant connections as bad within one RTT and begin to throttle them

Signaling Mechanism: Benefits

2. Decreases the transmission rate of malicious connections
 - FR-WARD must mitigate attack traffic as soon as possible
 - Passively checking compliance may not be fast enough

Signaling Mechanism: Benefits (cont.)

Signaling Mechanism

Throttling

3. Reduces energy consumption for benign connections
 - Reduces retransmission and increases goodput compared to throttling

Signaling Mechanism: Benefits (cont.)

4. The same signaling mechanism works across TCP variants
 - Signal achieves aforementioned benefits under each algorithm
 - Simplifies design of FR-WARD

Defending Against Smart Attackers

- An attacker may design an attack specifically to evade FR-WARD
 - (e.g.) an attacker could follow congestion control and comply with FR-WARD's signals
 - If FR-WARD only sends signals to initially mitigate the attack, the attacker could quickly return to a high sending rate
- FR-WARD defines an allowed transmission rate for each suspicious connection
 - Enforces this transmission rate until the attack agflow is relabeled normal

Defending Against Smart Attackers (cont.)

- FR-WARD employs the flow control mechanism of TCP to define a suspicious connection's allowed rate
 - In TCP, the receiver provides a flow control service in the form of a receive window, or *recw*
 - *recw* informs the sender the amount of available space in the receiver's buffer
- This provides a precise definition for FR-WARD's allowed transmission rate
 - If a sender transmits more than *recw*, the receiver's buffer will overflow, thus constituting a DDoS attack
- FR-WARD waits to observe *recw* values until after sending its initial signals
 - Utilizing flow control requires expensive operations and state maintenance
 - FR-WARD maintains the flow control state only when necessary

FR-WARD Overview

1. Attack Detection

- Detect an attack through victim-end collaboration
- Or self sufficiently detect an attack

FR-WARD Overview (cont.)

2. Labeling Procedure

- Label each connection in the attack agflow as good, bad, or suspicious

FR-WARD Overview (cont.)

2. Labeling Procedure

- Label each connection in the attack agflow as good, bad, or suspicious

FR-WARD Overview (cont.)

3. Signaling Mechanism

- Allow good, throttle bad, and send a signal to each suspicious connection

FR-WARD Overview (cont.)

3. Signaling Mechanism

- Relabel each non-compliant connection as bad

FR-WARD Overview (cont.)

4. Smart Attacker Defense

- Throttle any suspicious connections that attempt to send more than *recw*

Extending the Signaling Mechanism

- FR-WARD is based on aspects of TCP
 - Want to show that FR-WARD can extend to any type of connection
- Traditionally, an application uses UDP if unreliable communication is sufficient
 - (e.g.) if an IoT device wishes to send its location to a server, it can periodically provide the server its location with UDP datagrams
 - Even after a lost datagram, the server can still infer the device's location based on previous and future information
- FR-WARD does not need to provide an efficient response to such connections
 - It can simply throttle the connection since retransmission is not required

Extending the Signaling Mechanism (cont.)

- But, many IoT applications desire the reliability of TCP but with the overhead of UDP
 - (e.g.) CoAP, DTLS
 - These connections will retransmit lost packets similar to a TCP connection
 - FR-WARD cannot simply throttle these types of connections when they are labeled suspicious
- Any connection that requires reliable transportation uses some type of an acknowledgment
 - FR-WARD can create its signaling mechanism based on this acknowledgement

Signaling Mechanism: pCoCoA

Signaling Mechanism: pCoCoA

Signaling Mechanism: pCoCoA

3. Evaluation

- Effects on Benign Traffic
- Effects on Malicious Traffic

FR-WARD Evaluation

- We compare FR-WARD's performance against the previous source-end DDoS defense system, D-WARD
 - We expect FR-WARD to have the same accuracy and detection as D-WARD, so we do not evaluate them in this work
- We simulate mathematical models to estimate FR-WARD's effect on benign traffic
 - Retransmission, Goodput, Energy Consumption
- We use real-time experiments to estimate FR-WARD's ability to mitigate DDoS attacks
 - TCP SYN-flood attack, "Smart" TCP flood attack

Effects on Benign Traffic: Retransmission

- As the window size (at the time of the attack detection), increases, D-WARD drops more packets initially
 - FR-WARD never drops suspicious traffic, and causes close to zero retransmissions
- On average, FR-WARD reduces retransmissions by a factor of 203
-

Effects on Benign Traffic: Goodput

- As D-WARD drops more packets, it also causes the connection to slow down
 - Muddled with retransmissions, time wasted waiting for negative ACKs
- On average, FR-WARD increases goodput by a factor of 3.8

Effects on Benign Traffic: Energy Consumption

- Because FR-WARD reduces retransmissions, a benign device consumes much less energy than under D-WARD
 - Less packet transmission
- Because FR-WARD increases goodput, a benign device consumes much less energy than under D-WARD
 - Less active transmission time

Effects on Benign Traffic: D-WARD Parameters

(c) The magnitude FR-WARD improves Goodput under TCP NewReno. (c) The magnitude FR-WARD improves retransmissions under TCP NewReno.

- We evaluate the effect of D-WARD's parameter, f_{dec}
 - f_{dec} represents the rigor of D-WARD
 - (ie) How much traffic does D-WARD drop after a detected attack
- As D-WARD becomes stricter, it drops more segments
 - Increases retransmissions further
 - Decreases goodput further

Effects on Malicious Traffic

(a) The throughput of a naive attacker under D-WARD.

(d) The throughput of a naive attacker under FR-WARD.

- The naive attacker uses the hping3 command-line tool to flood the receiver with TCP-SYN segments
- After detecting an attack, both defense systems successfully throttle the attacker's throughput
- The graphs look almost identical
 - But FR-WARD's signaling mechanism allows a negligible extra *instant* of DDoS traffic

Effects on Malicious Traffic

(a) The throughput of the smart attacker under D-WARD.

(d) The throughput of the smart attacker under FR-WARD.

- The smart attacker follows TCP congestion control
 - But still attempts to flood the receiver with TCP segments
- The attacker can achieve bursts of successful DDoS traffic under D-WARD
 - The attacker follows congestion control but not flow control
- FR-WARD never allows the smart attacker to transmit more than the receiver can handle
 - The smart attacker either must transmit at a manageable rate or become detected
